In this project, I want to analyze the relationship between alcohol consumption and traffic accidents across 3 big cities (Istanbul, Ankara and Izmir) and 7 regions in Türkiye. Alcohol consumption is known to negatively affect attention, reaction time, and decision-making ability, which may increase the risk of traffic accidents. Therefore, I want to investigate whether regions with higher alcohol consumption also have higher numbers of traffic accidents. Understanding this relationship can help evaluate the impact of lifestyle habits on public safety and may provide useful insights for awareness policies.

For this project, I will combine two main datasets. First, I will use the **"Türkiye Health Survey dataset"** which is under **"Türkiye Stastistical Institue"** to obtain information about alcohol consumption levels across cities and regions. This dataset includes information about alcohol usage habits and demographic characteristics of individuals living in Türkiye. Second, I will use traffic accident statistics from "**Emniyet Genel Müdürlüğü"**, which provides data about the number of traffic accidents across different regions. By combining these two datasets, I will be able to compare alcohol consumption rates with accident frequency.

The final dataset will include regional observations where variables may include alcohol consumption rate, total number of traffic accidents, and population size. After collecting the data I will apply correlation analysis to examine whether there is a relationship between alcohol usage and traffic accidents. This project is original because it combines health behavior data with real-world accident outcomes in order to explore how lifestyle factors may influence public safety.
